

# C++ vec\_t class

Wednesday, October 13, 2010  
9:00 AM

- task: redo ray caster in C++

- lab 8: list\_t  $\leq$  data\_t

make sure you have  
the "big three":

- constructor
  - copy constructor (object(rhs))
  - assignment operator (=)
  - destructor, if needed  
(if constructor uses "new")
- the class

- today: Vec\_t class

lab 9: old lab 9 + lab 10 combined

- motivation:

```
#include <iostream>
#include "vector.h"
```

```
int main()
{
```

```
    vec_t v1(1.0, 2.0, 3.0);
    vec_t v2(4.0, 5.0, 6.0);
    vec_t v3, v4, v5(v2);
```

arr of +

vec\_t interface

this call, constructor

this call, constructor

```
vec_t (int ix=0.0, int iy=0.0, int iz=0.0)
{
    vec[0] = ix;
    vec[1] = iy;
    vec[2] = iz;
}
```

same fun name  
=> overloading

call, copy constructor:

```
vec_t (const vec_t & rhs)
{
    for (int i=0; i<3; i++)
        vec[i] = rhs[i];
}
```

: still in main

```
double vec_t::operator[] (int i)
{
    return vec[i];
}
```

```
std::cout << "Enter 3 vals" << std::endl;
std::cin >> v3;
```

should really do bound checking  
if (i >= 0 && i < 3)

```
friend std::istream & operator >> (std::istream & is, vec_t & rhs)
{
    // we are overloading the std::istream::operator >>
    // we don't do a deep copy of rhs info here
    // we let ... operator >>()
    // we let ... only vec_t class
}
```

we let  
ostream operator >> <<  
get out internally  
of vec\_t  
vec\_t class

```

std::ostream & operator<<(const vec_t & v) {
    return v.s >> v.rhs[0] >> v.rhs[1] >> v.rhs[2];
}

```

the std::ostream is not our object  
a deep copy of rhs into file

need this:  
vec\_t::operator()

in the vector.h header

```

double & operator()(int i) { return vec[i]; }

```

saw &  
can alter  
the type

MUTATION  
of i<sup>th</sup> element of our vec\_t

```
vec[0] = 5.3;
```

```
double val = vec[1];
```

what don't overload operator()

ACCESSOR of vec\_t

I don't want value changed. (const)

```

const double & operator()(int i) const {
    return vec[i];
}

```

back to main:

```

std::cout << "v1 = " << v1 << std::endl;

```

ostream operator <<

```

std::ostream & operator<<(std::ostream & s, const vec_t & v) {
    ...
}

```

```

std::ostream& operator<< (std::ostream& s, const vector<int>& v)
{
    s<< rhs[0]<< " " << rhs[1] << " " << rhs[2];
    return s;
}

```

result of operator:  
s << std::endl;

back in main:

```

v2[1] = 3.0;
v2[0] = v2[2];
} exercises our operator(),
  (both of them)

```

v4 = v1 - v3; → to get this to work,  
need to write

```

v4.operator = (v1.operator - (v3))

```

operator - ( )  
operator = ( )

if you can  
do this, write  
operator -  
operator +
